# Introduction

## 1 Derivative

- Chain rule

## 2 Integral

- Techniques of Integration
  - Substitution
  - Integration by parts

## Definition 1.1

Derivative of  $f(x)$  at  $x = a$  defined as:

$$\lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} = f'(a)$$

- Higher-order derivatives are defined as:

$$f'(x) = \frac{df(x)}{dx}, \quad f''(x) = \frac{d}{dx} \left( \frac{df(x)}{dx} \right) = \frac{d^2 f(x)}{dx^2}, \quad \dots,$$

And so

$$f^n(x) = \frac{d^n f(x)}{dx^n}$$

**Some important derivative formula is summarized as bellow:**

$$(f + g)' = f' + g' \quad (1)$$

$$(a.f)' = a.f' \quad (2)$$

$$(f.g)' = f'g + f.g' \quad (3)$$

$$\left(\frac{1}{f}\right)' = \frac{-f'}{f^2} \quad (4)$$

$$f'(a) = 0 \quad (5)$$

$$f'(ax) = a \quad (6)$$

$$\left(\frac{1}{af(x)}\right)' = \frac{-f'(x)}{(af(x))^2} \quad (7)$$

$$(a\sin(bx))' = ab\cos(bx) \quad (8)$$

$$(a\cos(bx))' = -ab\sin(bx) \quad (9)$$

$$(a\tan(bx))' = ab(1 + \tan^2(x)) \quad (10)$$

$$(a\cot(bx))' = -ab(1 + \cot^2(x)) \quad (11)$$

$$(e^{ax})' = ae^{ax} \quad (12)$$

$$(a \sinh(bx))' = ab \cosh(bx) \quad (13)$$

$$(a \cosh(bx))' = ab \sinh(bx) \quad (14)$$

$$(\sqrt{f(x)})' = \frac{f'(x)}{2\sqrt{f(x)}} \quad (15)$$

# Chain rule

The chain rule provides us a technique for finding the derivative of composite functions, with the number of functions that make up the composition determining how many differentiation steps are necessary.

## Definition 1.2

Suppose that  $x = g(t)$  and  $y = h(t)$  are differentiable functions of  $t$  and  $z = f(x, y)$  is a differentiable function of  $x$  and  $y$ . Then  $z = f(x(t), y(t))$  is a differentiable function of  $t$  and

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}$$

For example

$$f(g(x))' = g'(x) \cdot f'(g(x))$$

# Integral

- Integration can be used to find areas, volumes, central points and many useful things.
- It is necessary to mention that an Integral is the **reverse** of finding a Derivative

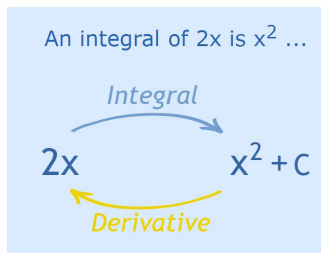

Figure: Integral vs Derivative

**Some important integration formula is summarized as bellow:**

$$\int u^n du = \frac{1}{n+1} u^{n+1} + c \quad (16)$$

$$\int \sin x dx = -\cos x + c \quad (17)$$

$$\int \cos x dx = \sin x + c \quad (18)$$

$$\int \frac{du}{u} = \ln |u| + c \quad (19)$$

$$\int a^u du = \frac{a^u}{\ln a} + c \quad (20)$$

$$\int \tan x dx = -\ln |\cos x| + c = \ln |\sec x| + c \quad (21)$$

$$\int \cot x dx = \ln |\sin x| \quad (22)$$

$$\int \frac{du}{1+u^2} = \tan^{-1} u + c \quad (23)$$

$$\int \frac{du}{\sqrt{1-u^2}} = \sin^{-1} u + c \quad (24)$$

# Substitution

Needless to say, most problems we encounter will not be so simple. Here's a slightly more complicated example: find

$$\int 2x \cos(x^2) dx.$$

This is not a “simple” derivative, but a little thought reveals that it must have come from an application of the chain rule. Multiplied on the “outside” is  $2x$ , which is the derivative of the “inside” function  $x^2$ . Checking:

$$\frac{d}{dx} \sin(x^2) = \cos(x^2) \frac{d}{dx} x^2 = 2x \cos(x^2),$$

so

$$\int 2x \cos(x^2) dx = \sin(x^2) + C$$

## Example 2.1

**Evaluate**  $\int x \sin(x^2) dx$ .

- First we compute the antiderivative, then evaluate the definite integral. Let  $u = x^2$  so  $du = 2x dx$  or  $x dx = du/2$ . Then

$$\int x \sin(x^2) dx = \int \frac{1}{2} \sin u du = \frac{1}{2}(-\cos u) + C = -\frac{1}{2} \cos(x^2) + C.$$

# Integration by parts

## Definition 2.1

**integration by parts** is a process that finds the integral of a product of functions in terms of the integral of the product of their derivative and antiderivative. It is frequently used to transform the antiderivative of a product of functions into an antiderivative for which a solution can be more easily found.

- Start with the product rule:

$$\frac{d}{dx}f(x)g(x) = f'(x)g(x) + f(x)g'(x).$$

- We can rewrite this as

$$f(x)g'(x) = \int f'(x)g(x)dx + \int f(x)g'(x)dx,$$

- and then

$$\int f(x)g'(x)dx = f(x)g(x) - \int f'(x)g(x)dx.$$

# Integration by parts

- If we let  $u = f(x)$  and  $v = g(x)$  then  $du = f'(x)dx$  and  $dv = g'(x)dx$  and

$$\int u dv = uv - \int v du.$$

- To use this technique we need to identify likely candidates for  $u = f(x)$  and  $dv = g'(x)dx$ .

## Example 2.2

**Evaluate**  $\int x \sin x dx$ .

- Let

$$u = x \xrightarrow{' } du = dx$$

$$dv = \sin x dx \xrightarrow{\int} v = -\cos x$$

- so

$$\int x \sin x dx = -x \cos x - \int -\cos x dx = -x \cos x + \sin x + C.$$
